# JOHN ARCHER, M. B.

OE

### MARYLAND.

Honored Sir,

IN offering you, in this public manner, the first fruits of a medical education, which has been pursued with so much pleasure under your direction, I feel a peculiar degree of satisfaction.

When I solicit you to receive this small publication as a testimony of my regard, I at the same time offer you my warmest thanks, for the paternal care with which you have conducted me, from the earliest period of my existence, to the present moment.

Accept, sir, my most fervent wishes for your health, for a continuance of that life which has been so eminently useful to others, and for your future happiness.

I am,
HONORED SIR,
Your fincerely affectionate
Son and Pupil,
70HN ARCHER, junr.

# ROBERT HARRIS, A. M.

FELLOW OF THE COLLEGE OF PHYSICIANS

OP

PHILADELPHIA, &c.

MUCH RESPECTED SIR,

PERMIT me thus publicly to return you my unfeigned acknowledgments, for the friendship and politeness you have on so many different occasions shewn me.

I beg you also, sir, will receive this as a small mark of my respect; and accept my numerous wishes for your prosperity.

I am,

RESPECTED Sir,

Your very affectionate

Friend and Kinfman,

JOHN ARCHER, junr.

# INTRODUCTION.

WHEN we take a retrospective view of the disease which affords the subject of the present dissertation; whether on the pages which physicians of the highest celebrity have lest behind them, or even within the narrow limits of our own immediate observation; we certainly cannot fail of being sensibly struck with the tyranny with which it has hitherto exercised its power, and the melancholy ravages it has committed upon hundreds of our species, while yet in the morning of life, notwithstanding every opposing effort of the most ingenious physicians.

ALTHOUGH I fondly cherish the pleasing hope, that the time will come (and I trust that time is not very far distant) when avenues to the grave will only be found through the medium of casualties, and old age, the uniform result of the sure and steady progress of time; I hope the reader will not conclude, that I consider myself as being able effectually to close up the passage which at present but too frequently exists, through the medium of the theme of this essay, by advancing a theory which shall lead to an uniformity of success in its treatment, or by laying down a mode of cure which shall invariably succeed.—I should rejoice were I able to present either.

B

The motives which led me to make Cynanche Trachealis the subject of my Inaugural Differtation, were my having had some opportunities of witnessing its progress, and marking a mode of treatment, which, from its general result, has been considerably more successful than any other on the records of medicine; and should it be a means of obviating its acknowledged fatality, in a single instance, it will indeed afford me an extensive source of pleasing satisfaction.

He who undertakes to recommend publicly a new remedy, or mode of treatment, must, at the same time, expect to have his observations frequently received with reluctance; nay, sometimes even the truth of his facts called in question. Authors and readers generally view things in different lights: the one oftentimes exaggerates, while the other frequently doubts too much. I have not exaggerated; I hope the reader will not doubt until he shall have sufficient reason.

WITHOUT a more prolix exordium, I shall now proceed to the immediate object of my Thesis. I regret much that the shortness of time allowed for preparing it, and the state of my health, prevented my rendering it more worthy the reader's attention: it is submitted with reluctance to his inspection: his liberality and candor will forgive the inaccuracies with which I am consident it abounds.

# INAUGURAL DISSERTATION, &c.

NOSOLOGY perhaps does not furnish a disease which has received a greater variety of appellations than the one under consideration: It is the Acute Asthma of Dr. Millar;\* the Catarrhus Suffocativus of Etmuller;† the Morbus Strangulatorius of Starr;† the Angina Polyposa, sive Membranacea of Professor Michælis; the Suffocatio Stridula of Dr. Home; the Cynanche Laryngea of Eller; the Cynanche Trachealis of Dr. Cullen, \*\* &c. &c. It is known by the vulgar names of Croup in Scotland; Chock or Stuffing in Ireland; and of Hives in different parts of the United States.

- \* Millar on Afthma and Hooping Cough.

- \*\* Cullen's First Lines, vol. 1.

FROM this variety of appellations, I have felected that of Cynanche Trachealis; not because I conceived it more proper than some of the others, but because the works of Dr. Cullen being in the hands of every one, the term must be familiar to all.

IT appears to be a difease to which the younger part of the human race is in a peculiar manner obnoxious: from the unequivocal instances, however, which Dr. Rush has related of its occurrence in the adult,\* (and I see no reason why, under particular circumstances, it may not appear in the adult subject) I can by no means subscribe to the opinion of those authors, who affert, that it only occurs within the first twelve years of life. I shall, however, consider myself sufficiently well supported by the concurring testimony of all writers, and from what little I have observed myself, when I say it occurs forty-nine times in children, (or perhaps a much larger majority) where it does once in the adult.

It is faid to be much more frequent in its appearance during the fpring and autumnal months. There is, however, no feafon of the year, fituation, nor climate, that does not afford fome difteresting spectacles of this terrible malady. Althorall situations afford proofs of its existence, there is,

<sup>\*</sup> Professor Rush's MS. Lectures.

in my opinion, sufficient reason to believe it is much more frequently found in those fituations, which, from their vicinity to marshes, rivers, and other bodies of water, are constantly under the influence of a cool, moistened atmosphere. Dr. Crawford mentions this difease as prevailing much in a wide plain, extending along the river Tay in Scotland, called the Carfe of Gowrie: \* this plain, we are told, has lately been dried up; fince which time the difease in that place has scarcely been known; and I know the difease takes place, in a far greater number of instances in the low marshy lands, called the Neck, fituated in that part of Maryland which lies between the Chefapeake Bay and Bush River, than it does in the upper lands, called the Forrest.

It is found in a high degree rapacious (if I be permitted the expression) of those children, who are by nature furnished with dispositions the most lively, with constitutions the most robust, and with health the most blooming.

WRITERS mostly represent it as being by far more frequent among children of the lower class; perhaps this may be the fact; but it is so far from being exclusively confined to the poorer children,

<sup>\*</sup> Thef. Inaug. Edin. 1770.

that it is (I had almost faid) a common disease in families of all ranks.

Some writers affirm that the Croup does not appear in children, while they are yet at the breafts of their mothers; but on the contrary we have the authority of Dr. Sauer in a letter to Dr. Michælis, when describing this disease, as it appeared epidemic at Wertheim, in the following words, which are directly in point, viz. "Infantes plurimos hoc morbo correptos vidi, qui adhuc macretor alibantur lacte." And Dr. Alexander, who has written an ingenious treatise on this disease, says, "Children, while at the breast, are not unfrequently attacked with it; and I have known three or four instances in which it has seized infants at the early period of fix months after birth."

A CIRCUMSTANCE respecting this disease has frequently struck me, that I dont find taken notice of by any writer; which is, that it seldom affects one child in a family, without appearing, at some after period, in at least some of the children, of the same common parents; this is probably owing more to a similarity of habit and constitution, than any other circumstance.

 <sup>\*</sup> Michælis, page 258.
 ‡ Alexander on Croup, page 13.

On the contagious nature of CYNANCHE TRA-CHEALIS, I can fay nothing from my own observation; it has been believed by a few; doubted by fome; and disbelieved by many. "This kind of fore throat," fays Dr. Rosen Von Rosenstein, when speaking of the CROUP, "has not only been spread at Stockholm; but likewise about Upsal, especially in the Rasbo parish, where, during the years 1761 and 1762, in many houses it carried off all the children; fome of them died on the fecond day: but the greatest number on the fourth and fifth days. They vomited up a quantity of slime and pieces of membrane. Neighbouring children, also, who vifited the place, got infected with the difease, and died foon after."\* This is fo extraordinary a paffage, that I should have been led very much to have doubted its authenticity, if Dr. Rosenstein were not a physician of such high respectability; and even believing in the authencity of the fact, I should have been induced to believe he had confounded it with CYNANCHE MALIGNA; for as the CYNANCHE TRACHEALIS is very far from being uniformly contagious, I can very eafily conceive, that the operation of the same causes might produce it in an hundred different instances, even within the limits of a fmall neighbourhood. I fay I should have doubted this paragraph of Dr. Rosenstein's; not

<sup>\*</sup> Sparman's translation of Rosenstein, page 294.

because I conceived it a thing impossible, or highly improbable, but because I had never seen it contagious myself, and because authors of much veracity had declared to the contrary. Dr. Rutty mentions this disease as being epidemic in Ireland;\* but does not say it was contagious. Dr. Barton lately informed me, that in the latter end of the year 1793, the HIVES prevailed much in Philadelphia; and from several unequivocal cases, there was no doubt left with him as to its contagious nature.

Physicians have cavilled not a little concerning the inflammatory nature of Cynanche Trache-Alis; fome confidering it as a well marked inflammatory difeafe, while others view it as entirely unconnected with even a common fymptom of inflammation. As I do conceive it, in many inflances, altogether fymptomatic of a general difeafed action of the fanguiferous fyftem—and as I confider it, in a variety of inflances, by no means less frequent, a local and primary difeafe of the Trachea, with the different phenomena of fever, mere fymptoms; I am naturally led to confider it in two different points of view, and with this intention, for the fake of perfpicuity, I shall treat of each separately, under the heads of,

- 1. CYNANCHE TRACHEALIS SYMPTOMATICA, &
- 2. CYNANCHE TRACHEALIS IDIOPATHICA.

<sup>\*</sup> Rutty's Chronological History of the Weather.

# 1. CYNANCHE TRACHEALIS SYMPTO: MATICA.

COULD we produce no proofs in support of this disease being frequently the mere consequences of excessive morbid action in the arterial system at large, we should be led to suppose nothing more probable, from the acknowledged truth of the following positions, 1. That from a variety of causes, almost every part of the body is liable to debility-2. That this debility is as uniformly accompanied with increased excitability-3. That 'this increased excitability, will be readily changed into morbid excitement, by causes of an exciting nature -and, 4. That this increased excitement is always most violent, where the excitability is most abundantly accumulated .- I fay, had we no further proofs of Croup, being oftentimes a mere fymptom of general disease, than these important and firmly established laws of the animal œconomy, we should be warranted in concluding it a thing extremely possible; but when the causes, symptoms, and mode of treating this state of HIVES, stand as fuch firm barriers in support of these principles; the most rigid sceptic can no longer withhold his belief.

DR. RUSH, the learned and ingenious Professor of the Institutes of Medicine, &c. whose authority is

at all times of the most superior kind, considers it as an inflammatory disease, and very properly ranks it as a grade of the Anginose State of Fever.\* Dr. Frank has emphatically called it Tracheitis;† and Dr. Darwin, whose ingenuity is admired by all, has called it Peripheumonia Trachealis;† this term, as shewing its inflammatory nature, is very good; but within itself, it is undoubtedly exceptionable.

In support of the inflammatory nature of this disease, Dr. Rush relates the case of Dr. Foulke, in whom a true Cynanche Trachealis occurred from a translation of Rheumatism.

Much has been faid against its being an inflammatory disease, because dissections so seldom discover any marks of inflammation. There are, however, dissections on record to prove that inflammation is sometimes found; § but even if no marks of inflammation were sound on dissection, it would not, in my opinion, go in the smallest degree to prove the contrary; for I can very easily conceive,

(and nothing indeed appears to me more probable) that the veffels may be fo far relieved by an effusion, that not even the veftige of such a state shall be lest behind. Now we know very well, children seldom die of this disease, until the vessels have in some instances nearly, and in others entirely, relieved themselves by effusion; of course are opened only in this situation. Could we by any means have a view of the interior of the trachea, before this effusion has taken place, I make not the smallest doubt but we should in many instances find instanmation accurately marked.

## DEFINITION.

I WOULD define this state of CYNANCHE TRA-CHEALIS to be a fever, accompanied with a stridulous respiration, sonorous cough, and with scarcely any apparent tumor or inflammation in the fauces.

#### SYMPTOMS.

IN the generality of cases, this state of HIVES is ushered in with the usual phænomena of sever; such as slight shiverings, alternated with heat, languor, and other symptoms, indicating the presence of a febrile state of the system; a slight degree of hoarseness follows, accompanied with a dry cough,

unattended for the most part with expectoration; and the whole bears so striking a similarity to a common Cold as to be almost universally mistaken for one.

Thus this infidious difease advances; the tongue becomes white; appetite is lost; respiration much hurried; and the Pulse, which Dr. Rush has elegantly called the INDEX of the fystem, \* when reforted to for information, feldom fails discovering to the physician, that a wrong action is going on in the blood vessels. There is commonly a degree of foreness complained of about the larynx, but very feldom attended with fwelling or inflammation; deglutition is fcarcely at all affected; much reftleffnefs and anxiety prevail; eruptions fometimes appear on different parts of the body; voice is shrill and sharp; the face becomes flushed and turgid with blood; hoarfenefs and cough advance in violence; the latter is followed by a found fo peculiarly shrill, that I can compare it to nothing more aptly than a note emitted from a highly toned instrument. The muscles of the abdomen and thorax are thrown into fuch violent action by the respiring efforts of the patient, that no doubt is left as to the existence of a mechanical obstruction in the

<sup>\*</sup> Professor Rush's MS. Lectures.

<sup>†</sup> Vox acuta, clangofa, fibilans, BOERHAAVE.

trachea. The found emitted during inspiration has been compared to the croaking noise made by a young hen,‡ to the crowing of a cock, and to the barking of a dog or fox. I think it resembles the found of air forcibly drawn through a small aperture, more than any thing I know. Eyes become languid and hollow; tongue and throat dry and parched. Respiration is evidently much worse by paroxysms; this is most probably owing to the irritation of the foreign membrane in the trachea, exciting the muscles of the glottis into a spasmodic action; which, by still farther diminishing the opening through the rima glottidis, is necessarily followed by respiration more laborious, and that after intervals of less difficulty.

Thus this truly diffressing disease proceeds in its melancholy career, and is succeeded by a train of symptoms, which only add to the well sounded alarm of parents and attendants. The countenance, in some instances, becomes pallid, in others it puts on a full and livid hue, owing to the returning blood being denied a free passage through the lungs to different parts of the body from the right side of the heart, in consequence of an almost totally obstructed respiration. The patient becomes

<sup>‡</sup> Michælis de Angina Polypofa, &c.

<sup>|</sup> Home's Inquiry, &c.

<sup>§</sup> Rufli's Inq. and Obferv. vol. 1.

drowfy, but is prevented fleeping from the violent exertions of the respiratory organs; the system becomes exhausted; the pulse languid and tremulous; coughing can no longer be effected; the eyes are overspread with a pellicle of a glairy appearance; convulsions frequently come on, and the unhappy sufferer expires under all the phænomena of actual strangulation.

SUCH is the general rife, progress, and termination of the Cynanche Trachealis Symptomatica, though it not unfrequently attacks with all the suddenness and alarming violence of an apoplectic paroxysm; and this most generally while under the pleasing influence of refreshing sleep.

This difease runs its course in different periods of time; it often destroys the patient in four and twenty hours from the first attack; more frequently it terminates in two, three, and four days; and, if we believe some authors, it is protracted even twelve and fourteen days. "Totus morbi," says Dr. Sauer, "decursus raro ultra 2. 3. nunquam "ultra 4. diem protractus est. Plurimi secundo jam peribant die."\*

THE immediate cause of these grievous symptoms, dissections have proven to be in the trachea,

<sup>\*</sup> Michælis de Angina Pelypofa, &c. page 258.

commencing from above, and proceeding down even into its most minute ramifications. The largest quantity of the effused sluid has been, I believe, most generally found on the posterior surface of the aspera arteria, where the parts are entirely membranous, and plentifully supplied with excretory ducts, for the passage of secreted mucus.

Many different opinions are held respecting the nature of the preternatural membrane, found lining the interior of the trachea; for while some consider it as inspissated mucus,\* others contend that it is coagulable lymph; † and Dr. Caldwell, who thinks it different from both mucus and coagulable lymph, supposes it to be a substance fui generis.† Decisive experiments, I believe, have never been made to prove what it is. It is a point of controversy, on which I feel myself wholly unprepared to decide. I am far, however, from supposing it "a substance fui generis;" but I can, without the smallest difficulty, conceive, that it may at one time be inspissated mucus, and at ano-

ther coagulable lymph. We have analogies in favour of each, in different parts of the fystem, under certain circumstances.

## DIAGNOSIS.

THIS difease so much resembles a common Cold in its commencement, that it has almost uniformly been mistaken for one. It may, however, be distinguished from a Cold, by being most generally unattended with sneezing, and defluxions from the eyes and nose, and by the Croup being accompanied with a peculiar sonorous cough, and a shrill, sharp voice. As it advances, every doubt is removed.

IT cannot be mistaken for Hooping Cough. It is much more seldom contagious than that disease. Hooping Cough is attended with paroxysms very evident and violent, and during the intermissions, is not attended with the stridulous respiration of the Hives.

A VIEW of the internal fauces, will readily fatisfy the most superficial observer, that it is neither CV-NANCHE TONSILLARIS, nor MALIGNA: they are accompanied with much pain, and difficulty of swallowing from the inslamed and tumid state of the tonsils; and are not attended with the croupy inspiration.

## REMOTE CAUSES.

THESE are all fuch as induce debility, either disrectly, or indirectly.

Among those which act directly, are,

- 1. COLD. Cold, especially when combined with moisture, I believe to be by far the most frequent remote cause of Cynanche Trachealis. Hence we find it more frequently occurring in those situations, and seasons, which afford a cold, damp atmosphere. With the general debilitating effects of cold, it has a particular local action on the trachea.
- 2. PRECEDING DISEASES, as Small-Pox, Meazles, Catarrhal affections, Hooping Cough, and Apthæ—they all produce a debility, that disposes much to Cynanche Trachealis.

OTHER causes, by acting directly, may predispose to this disease; but those I have mentioned are much the most common.

Those causes which act indirectly in predisposing to the disease, are,

I. HEAT.

- 2. FATIGUE, whether induced by bodily exercise, or excessive crying, predisposes the system to an attack of this disease. Crying acts both generally and locally.
- 3. Contagion. This I rank as a remote cause; not from my own observation, but upon the authorities of Dr. Rosenstein, and Professor Barton.\*—&c. &c.

## PREDISPOSING CAUSE.

THE predifposing cause of this disease, as well as all other sebrile diseases, as fully illustrated by Dr. Rush, is—Debility.

## EXCITING CAUSES.

THE exciting causes are stimuli of all kinds, as

- 1. HEAT. Heat, succeeding cold, I believe to be much the most frequent exciting cause of CYNANCHE TRACHEALIS.
  - 2. CONTAGION.
- 3. Dentition—may very properly be mentioned here.

<sup>\*</sup> See a preceding page. † Rush's Works.

4. A SALINE ATMOSPHERE, when this difease occurs near the sea coast, is mentioned by Dr. Home, as a cause.\*

In fact, any thing, which will excite the fystem into action, may, with propriety, be ranked under the head of exciting causes.

## PROXIMATE CAUSE.

VARIOUS, indeed, have been the fentiments of authors, respecting the proximate cause of Cy-NANCHE TRACHEALIS; various, however, as they have been, none appear to me, by any means fatisfactory. I can consider the proximate cause, and disease, in no other light, than as different terms, expressive in the end of the same thing; for if we define the proximate cause of a disease, we have a definition of the difease itself; with this difference alone, that in our definitions of diseases, we include the most prominent effects of their proximate cause. Can we then suppose this state of CYNANCHE TRA-CHEALIS to confift in an increased secretion, or in a inembrane formed in the trachea, &c.? By no means. From our view of the subject, these will, certainly, appear to be no more than mere effects of the disease, or, in other words, of the proximate

<sup>\*</sup> Home's Inquiry &c. page 40.

cause. Those physicians, therefore, who will now hold forth such proximate causes, are, in my opinion,

"Just like the Indian, whose untutored mind,

"Sees God in clouds, or hears him in the wind."

POPE.

FROM what I have faid, and as I have given a description of the disease, the reader will no doubt suppose I am not going to give any proximate cause: I certainly think it unnecessary; yet, as it is so customary, I slatter myself, he will, with me, view the proximate cause of this state of Croup, as consisting in a preternatural excitement, accompanied with irregular, or convulsed action in the arterial system, but determined, in a more particular manner, to the trachea, and its bronchial ramissications.

### PROGNOSIS.

THERE is perhaps no way, in which physicians have more frequently exposed themselves to the contempt and ridicule of the world, than in the prognosis of diseases. They should avoid deciding positively, as to the event of any disease; "For it is impossible," says Dr. Rush, "in acute diseases, to tell where life ends, and where death begins. Hundreds of patients have recovered, who have

been pronounced incurable, to the great difgrace of the profession."\*

More danger is always to be apprehended, when this difease attacks suddenly and violently. The greater the sever, and the more difficult the respiration, the more hazardous are we to esteem the event. Should the reverse of these occur, with a cough attended with expectoration; especially should they take place after the use of the medicines to be hereafter recommended; we may give encouragement on good grounds. I should always be backward in pronouncing an unfavorable prognostic, unless symptoms of the most extreme danger appeared; such as quick, short, and difficult respiration; inability to swallow; weak, tremulous pulse; fainting; coldness of the extremities, and convulsions.

### METHOD OF CURE.

IN proceeding to the mode of treating this state of Cynanche Trachealis, our indications will naturally be—

- 1. To moderate and remove the fever.
- 2. To remove the preternatural membrane in the trachea.

<sup>\*</sup> Rufh's Inq. and Observ. vol 1.

3. To prevent a return of the disease.

To answer the first intention, the most effectual remedy is,

- 1. BLOOD-LETTING. All authors concur in the propriety of using the LANCET; and here I cannot but regret the mistakes parents have been led into, by confidering this difease as nothing more than a common Cold; they delay taking the advice of a physician until the disease has increased in violence, and relieved itself, to a considerable degree, by a discharge, which, in a great measure, blocks up the very passage through which life is carried on. There is feldom any call for this invaluable remedy after the formation of the membrane; of this, however, I will by no means speak positively; for we must, at all times, judge of this from existing circumstances. It should be used in the earliest stages of the disease; the frequency of its repetition, and the quantity of blood to be drawn, must, at all times, be left to the discretion of the physician: all he will have to do, will be, to attend to the pulse, and state of the system; these done, it will be impossible for him to err.
- 2. Purges. These, as a remedy for reducing action in the system, are acknowledged by all; but in this disease, so much can be effected by the use

of the Lancet, that those which will keep the bowels moderately open will be sufficient, and for this purpose, Magnesia, Jalap, Epsom or Glauber's Salts, would be sufficient; but I should much rather preser Calomel in small doses, for at the same time that it acts as a laxative, it determines to the surface.

3. DIAPHORETICS. These should be of a kind which will stimulate as little as possible. Tartarized Antimony exhibited in such doses as will keep up a moderate degree of nausea, will answer the intention extremely well; it may be combined with a small quantity of NITRE.

Such are the evacuants necessary for reducing the febrile state of the system, particularly during the commencing period of the disease.

BLISTERS have been warmly recommended in CROUP. The intention of diverting inflammation from an internal to an external, less dangerous part, is undoubtedly a good one. The remedies already laid down, will be sufficient during the first period of the disease, the only time blisters promise to do any service. In the latter stage I do not hesitate to say they are useless.

The fecond indication is, to remove the preternatural membrane from the trachea and its ramifications, the bronchiæ. To effect the removal of this membrane, has long been looked upon as an important defideratum in the cure of Cynanche Trachealis. It is at this time (at least in the country) physicians are generally called upon to be spectators of the dreadful sufferings of the tender part of the human race: 'tis then, and not till then, when the unfortunate sufferer is gasping for breath, and suffocation appears to be almost inevitable, that medical aid is requested.

For the feparation and ejection of this membrane, many different methods have been proposed; but I am forry to add, they have been but too frequently ineffectual; as most authors candidly acknowledge impracticable.

From what little opportunity I have had of obferving myself, and from the extensive experience of others; I take particular pleasure in recommending a medicine, which has the surprising powers of dislodging the foreign membrane, that lines the interior parietes of the trachea. When I recommend this medicine, I am warranted in recommending it with considence; for its good effects support my recommendations, and I do conceive that if administered with that regularity and attention, necessary

in the exhibition of all medicines, it will so often fucceed, that others will not be backward in extolling it as highly as I have myself. The medicine I allude to is the SENECA SNAKE ROOT of our country.\* It was first used by my Father, about seven or eight years ago, in a well marked case of CROUP. far advanced, and with fuccess; after the common remedies had been fedulously administered, without the smallest degree of relief: since that time it has been repeatedly used by him, others, and myself with a fimilar refult. I am induced to believe, it will fcarcely ever fail, when given in the forming state of the membrane; and I am confident it will fucceed in a majority of cases after a complete formation of the membrane. The decoction of the root, is the manner in which I have generally feen it used; the strength must be determined by the physician; it must be so strong, as to act sensibly on his own fauces, in exciting coughing, &c. for in this disease the larynx in a great measure loses its natural sensibility.† Half an ounce of the root of SENECA, bruised, and simmered in a close vessel, in half a pint of water, until reduced to four ounces, will probably in most cases be sufficiently strong. A teaspoonful of this to be given every half hour, or hour, as the urgency of the fymptoms may demand;

<sup>\*</sup> Polygala Senega of Linnæus.

<sup>†</sup> Dr. Geo. Monro's Thef. Inaug. Edinb. 1786

and during these intervals a few drops occasionally, to keep up a fensible action of the medicine in the fauces, until it act as an emetic or cathartic; then repeated in small quantities, and so frequently as to keep up a constant stimulus in the mouth and throat. By these means, in the course of two, four, fix or eight hours, a membrane is oftentimes discharged by the mouth, one, two, and three inches in length; fometimes it is fwallowed and voided by stool. Patients who use the medicine should not be permitted to drink any thing whatever, for some minutes after each dose. The reason must be obvious to all. The powder has lately been used,\* in doses of four or five grains, mixed in a little water, with effects equally pleafing as the decoction, and more fo, unless the latter have been carefully prepared.

To account for the action of the Seneca, is a fubject necessary to be inquired into. When taken into the mouth, and swallowed, its pungency is immediately found to be highly diffusive; it quickly excites an almost continual coughing, with repeated efforts to swallow, and promotes a plentiful secretion of saliva. In my opinion, its operation in curing Croup is chiefly local. Does this consist in a discharge being excited between the membrane and the trachea, which, from being less adhesive,

<sup>\*</sup> By the author's FATHER and BROTHER.

the whole is readily removed by expectoration, in confequence of the coughing, which is fimultaneously induced; or by vomiting, when the Senech acts as an emetic?—Dies doceat.

Some will no doubt fay, it acts in curing this difease merely from its emetic and diaphoretic properties. It would be sufficient for me to ask those gentlemen, why other emetics and diaphoretics will not effect the same purpose. I have in some instances seen it effect a cure, without either acting as an emetic, diaphoretic, or cathartic. Does it not then cure Cynanche Trachealis, chiefly by acting as a local stimulant?

SHOULD the disease be far advanced, and danger appear pressing, CALOMEL, as co-operating with the SENECA, may be used advantageously; it should be given freely internally, and mercurial frictions applied externally to the throat and adjacent parts.

If the limits of this differtation permitted, I could relate many unequivocal cases of the disease, in which the use of the Seneca was followed by the happiest effects. I shall, therefore, only detain the reader with a recital of one or two.

### CASE I.

IN the autumn of 1796, I visited Miss F-L\_\_\_\_, about three years of age, of a full, gross habit. She had been feized, two days previous to my vifit, with the usual phænomena of symptomatic Croup. Her breathing was now wheezing, and very laborious; inspiration croupy; cough dry and fonorous; pulse quick and frequent; but discovered fcarcely any inflammation; anxiety and reftlefsnefs were extreme. I immediately ordered the decoction of Seneca, as directed in a former page; and the use of CALOMEL to open her bowels. The SENECA, quickly excited coughing, with repeated attempts to fwallow, and retchings to vomit. In the course of an hour or two, a quantity of viscid phlegm was expectorated, and in a few hours, pieces of crusted membrane were discharged; a much more eafy respiration took place, and in fixteen or eighteen hours I had the pleasure of seeing her as well as ufual.

#### CASE II.

IN the spring of 1796, I saw the son of Mr. J—— E——, aged three years. He had had the HIVES, about six months before, and was perfectly relieved by the use of Seneca, and Calomel. The stridulous respiration was distinctly marked, and the parents alarmed, applied as foon as they observed this, as they faid, "certain token of danger." I did not find it necessary to do more than open the bowels, and make use of the Seneca; which perfectly restored him in 24 hours.

THE third object of our attention, is to prevent a return of the difease.

To fulfil this intention, we should, in the first place, if necessary, endeavour to restore the strength of the patient; and, for this purpose, a decoction, or vinous insusion of the Peruvian Bark, together with a diet accommodated to the state of the system, will at all times be sufficient. The patient should be removed from the place where the disease was received, (if the state of the atmosphere, from its vicinity to marshes or faline waters, be suspected as a cause of the disease) to a pure and dry air. The bowels should be kept open by the occasional use of a little Calomel; and possibly a moderate perspiration kept up by the use of the warm bath, as recommended by Dr. Monro, might be attended with advantage.\*

WITH this I leave the CYNANCHE TRACHEALIS SYMPTOMATICA, and proceed to the confideration of the CYNANCHE TRACHEALIS IDIOPATHICA.

<sup>\*</sup> Dr. George Monro's Thef. Inaug. Edin. 1786.

# 2. CYNANCHE TRACHEALIS IDIOPA-THICA.

THAT there is a ftate of CYNANCHE TRACHE-ALIS, of frequent occurrence, purely local, and independent of any general affection whatever, is in my opinion, a truth fufficiently well established.

CHILDREN appear to abound with the different fluids in a much larger proportion than the adult, and all their excretions are very copious, particularly from the glands, which abundantly exist on the internal surface of the trachea, and from its ramifications, the bronchiæ. Now it will, by no means, be a difficult matter to conceive that this mucus may, from the more liquid parts being partly absorbed, and partly dissipated by the air of respiration, become consolidated in the form of a perfect membrane; and accordingly, I believe it to be a fact, upon which we may with safety rest our belief.

"THE veffels of the trachea and bronchiæ," fays Dr. Rush, "always abound with a thin "mucus, which is poured into them, in proportion as they are irritated by inflammation, or the action of the external air. Children abound "with a greater quantity of fluids in these parts than adults, and when it is accumulated in the

"trachea and bronchize in a greater quantity than ordinary, it is easy to conceive in what manner it is converted into a membrane after its more fluid parts are dissipated. We have an analogy of this in the nose. Were the passages of this organ less within our reach, it is probable a membrane resembling that found in the trachea, would be found in it every four and twenty hours," &c.†

An increased secretion of mucus, whether from an increased action or relaxation in the vessels of the part, may be called in to account for the presence of mucus in the trachea and bronchiæ, without advancing opinions, by any means hazardous. I believe, however, that even the ordinary secretion of mucus, if retained, either from inattention or inability to evacuate it, will, from the more fluid parts being removed, oftentimes be sufficient to account for the disease. Each of the three ways have, I am consident, produced the membrane in the trachea.

THE fever in this state of CYNANCHE TRACHEA-LIS, is by no means a uniform occurrence, and when it does appear, instead of being the *primary* affection, is in reality a mere subsequent *effect*. Dr. Sauer, in a letter to Professor Michælis says, "Fe-

" bris initio nulla;" and, " I acknowledge," fays Dr. Rush, "that I have generally seen both " fpecies that have been mentioned, (fpeaking of the Cynanche Trachealis spasmodica, and humida) " without inflammatory fymptoms, and fometimes " without fever, especially in the first stage of "the diforder." † Phlegm is fometimes heard evidently to rattle in the trachea and bronchial veffels, but more frequently a cough, fometimes moist, at other times dry, accompanied with a wheezing, difficult breathing, are first observed; the voice becomes harsh and shrill, appetite is feldom impaired, and during every respite that may occur to the labored and hurried respiration, the patient appears, even in very advanced periods of the difease, to be cheerful, lively, and nearly free from complaint.

As the disease advances, breathing becomes difficult in the extreme; inspiration is in every respect as described in the symptomatic state. The cough is now dry and sonorous; a degree of soreness is complained of about the larynx; deglutition is scarcely affected; the face puts on a full, slushed appearance; heat and thirst are considerable; pulse quick and frequent, but seldom discovers much hardness, fullness, or tension.

<sup>\*</sup> Michælis, page 258.

<sup>†</sup> Rush's Inq. and Observ. vol. 1,

#### CASE.

IN the winter of 1795, I saw the servant child of Mr. S L She had been, for two days, observed to have a wheezing, difficult respiration; peculiar dry hoarfe cough; but as no fymptom of fever preceded, or attended, as her appetite was not impaired, and as she appeared nearly as lively and cheerful as usual, no alarm was excited. These fymptoms, however, advanced to fuch a pitch of violence on the third day, that death appeard to be pointed out, as the inevitable termination of the difeafe. The peculiar infpiration which attends this complaint, and which most authors view as a pathognomonic fymptom, was very striking in the present case. I immediately exhibited an emetic; but without any relief. I then purged her with CALOMEL, and gave the SENECA in the usual manner. In eight or ten hours there was confiderable relief to the laborious breathing, and scarcely any expectoration was observed; in eighteen or twenty hours, pieces of white membrane were voided by stool; and, in thirty hours, I was pleafed to leave her as well as ufual.

I SHALL here take the liberty of reciting an extract from a letter, I, a few days fince, received from my brother, Dr. Thomas Archer.

"I PERFECTLY agree with you, in supposing there are two states of CYNANCHE TRACHEALIS; for I have witnessed the rise, progress and termination of the disease in many cases, entirely free from sever, and vice versa.

"I HAVE in (I may fay) numberless instances effected a cure of CROUP, by SENECA alone; and I have lost many children who were treated in the common way.

" P \_\_\_\_ T \_\_\_ Efquire's daughter, about four years old, was feized with the usual symptoms of CROUP: in 36 hours after seizure, I was sent for, and found her laboring under the most violent fymptoms of that difease, a dry, sonorous cough, without expectoration. The muscles of the thorax and abdomen were thrown into violent convulfive actions, by the efforts of difficult respiration. Pulse natural, and appeared hurried, chiefly from the difficulty of breathing. An ounce of the root of SENECA bruifed, was fimmered from a pint to half a pint of water; of this a teaspoonful was given every fifteen or twenty minutes. In lefs than an hour, a discharge of viscid phlegm took place, in large quantities; respiration became more natural, and in a few hours the stridulous breathing was entirely removed. Before I left her, which was in 24 hours after feeing her, she was up, and playing with her playmates.

"I WOULD not" (he adds) "give an ounce of SENECA as a chance in the cure of CROUP, for all the Emetic Tartar, Mercury, and Cantharides in the United States."

Onions, and Garlic, in different forms, may be given advantageously; also strong Coffee, as recommended by Dr. Barton.\*

Our *next* indication is, to prevent a return of the difeafe.

If the patient be much reduced by the length, or violence of the disease, a decoction, or vinous infusion of Peruvian Bark, with a generous diet, may be allowed; and the patient should be removed into a dry, pleasant atmosphere.

WITH this then, I finish my Inaugural Differtation; but before I close it entirely, I beg you, IL-LUSTRIOUS PROFESSORS, who have so eminently distinguished yourselves in teaching the science of

<sup>\*</sup> Essay towards a Materia Medica.

medicine, in its different extensive branches, and from whom I am now about to receive the highest honors of the profession, will accept my most cordial wishes for your happiness; and be assured, that for the many instances of friendship you have on many occasions shewn me, as well in a private as public capacity, I shall ever retain a heart-felt remembrance.

Dum juga montis aper, fluvios dum piscis amabit, Dumq: thymo, pascentur apes, dum rore cicadæ; Semper honores, nomenaq: tua, laudesq: manebunt.

VIRGIL.

THE END.

To these succeed the more distressing symptoms of short, quick and difficult breathing; the eyes become languid, sunk, and deadly; a cold clammy sweat breaks out; the pulse becomes weak, trembling, and almost imperceptible, when the miserable patient expires from actual suffocation.

## CAUSES.

THE causes of this state of Croup, are, whatever disposes to a more plentiful secretion of mucus; such as,

- 1. INFANCY. Hence its frequent occurrence at this period of life.
  - 2. Cold, and Moisture.
  - 3. A SALINE ATMOSPHERE:
  - 4. DENTITION, &c. &c. &c.

## DIAGNOSIS.

IN the Diagnosis of this state of *Croup*, it will be sufficient to distinguish it from the former, and in this, there will be no kind of difficulty. A history of the symptoms will always inform us whether it commenced with fever; and attention to the pulse

will let us know, whether an inflammatory action exist in the blood vessels; if neither, we may with confidence conclude it to be of the idiopathic kind.

As we fufficiently well know, from what has been already faid, in what this state of Hrves consists, I shall forbear detaining the reader with the proximate cause, for it would be nothing more than mere repetition.

#### METHOD OF CURE.

IN the treatment of this state of CYNANCHE TRACHEALIS, our indications must be,

- 1- To remove the mucus, or diflodge the membrane from the aspera arteria, and its ramifications.
  - 2. To prevent a return of the disease.

In order to fulfil the first intention, I am of opinion, nothing more will be necessary, than to administer the decoction of Seneca, as directed in a former part of this essay. It will generally be sufficient, I am consident, without any other medicine. The use of Mercury may, however, as in the symptomatic kind, be sometimes necessary; for, in advanced stages of the disease, all our efforts combined, are sometimes inessectual in affording relief.
